C Structural Topic Models

Number of Topics Choice

We estimate our topic model using the STM package in R (Roberts et al., 2019), after having applied a pretty standard pre-processing to our corpus. For each time-frame considered, we evaluated 13 models, varying the number of topics k from 3 to 15, and found that models with relatively many topics performed better in terms of held-out likelihood. After a qualitative inspection of the most representative words and documents for each topic in this range, we thus selected $k=14$. Note that when STM models include a content covariate, in our case *Gender*, it is not possible to calculate the model's exclusivity. Given that evaluating semantic coherence is useful only when in combination with semantic exclusivity (Roberts et al. 2019), we opted for using only held-out likelihood (and its opposite, the model's residuals). Figures 6-8 show the levels of held-out likelihood for models with $k=3$ to 15, for the three time-frames 1948-1973, 1974-1999, and 2000-2020). Held-out likelihood (residuals) increases (decrease) steadily until $k=14$, and it flattens afterwards. For a similar approach, please see Decadri and Negri (2024).
